**(54) Title:** MULTIPLE BIOPSY SAMPLING CORING DEVICE

**(57) Abstract**

This invention is a device and method for collecting a sample tissue comprising a device body (16) having a forward facing tissue opening, a severing element (22) to sever tissue within the opening, and a storage space (25) to store multiple tissue samples.

MULTIPLE BIOPSY SAMPLING CORING DEVICEField of the Invention

This invention relates to taking samples of tissue  
5 from the body for biopsy analysis.

Background of the Invention

Tissue samples can be examined in a laboratory to  
determine the presence of a pathological disorder (e.g.  
malignancy). Often, the samples must be obtained from  
10 deep within the body using a medical sampling instrument.  
It is usually best to obtain several samples around the  
location where the disorder is suspected so that the  
presence and progress of disease, if any, can be  
accurately determined. The samples must be catalogued  
15 according to the location from which each sample is taken  
and the integrity of the samples must be maintained for  
the subsequent laboratory analysis.

Summary of the Invention

In a first aspect, the invention features a device  
20 for collecting from a tissue surface, a sample of tissue,  
including tissue specimens, polyps, or the like. The  
device includes a device body defining a forward-facing  
tissue receiving opening of substantially predetermined  
width through which tissue may pass when the opening is  
25 near the tissue surface. A severing element is  
actuatable across the tissue receiving opening when  
tissue from the surface extends through the opening for  
severing the tissue from the surface. A storage space  
proximal of and adjacent the opening is provided for  
30 storage of multiple, successively taken samples by  
repeatedly passing tissue through the opening and  
actuating the severing element.

Embodiments may include one or more of the  
following features. The severing element is a set of  
35 moveable jaw-like cutting members actuatable to be opened

- 2 -

and closed for severing tissue from the surface to take the sample. The cutting members are coaxially disposed and axially positionable with respect to the tissue receiving opening such that the device is positionable

5 between a first configuration in which the cutting members are proximal of the opening and open for receiving tissue through the opening and a second configuration in which the cutting members are near the opening where the cutting members can be closed to sever

10 tissue and take the sample. The cutting members are disposed over the device body. The cutting members are biased toward the closed configuration. The cutting members are opened by positioning the device in the first configuration, where the cutting members bear on outer

15 surfaces of the body which oppose the bias force. The cutting members are closed by positioning the device in the second configuration where the cutting members are free from the body and close in response to the bias force. The forward-facing tissue-receiving opening is

20 defined about its periphery by a tissue-cutting edge, where the tissue passes through the opening by urging the edge distally into the tissue surface. The device includes an axially movable retractor for engaging tissue and drawing it proximally. The retractor is extendable

25 distally beyond the opening for engaging the tissue surface and retractable proximally to draw tissue through the tissue-receiving opening. The retractor is a spear-form element adapted to pierce tissue and has a retaining barb on its distal end. The severing element is a

30 cutting loop, the cutting loop is actuatable between an open configuration that is oriented generally coaxially with the body defining the tissue-receiving opening and a closed configuration in which the loop passes across the opening to sever the tissue. The cutting loop is

35 actuated by a control wire extending parallel with the

- 3 -

axis of the body. The control wire passes through a lumen extending to an opening adjacent the tissue-receiving opening. The cutting loop is actuated by withdrawing it into the lumen. The retractor is

5 extendable distally beyond the opening and the cutting loop for engaging the tissue surface and retractable proximally to draw tissue through the tissue-receiving opening and cutting loop. The retractor is a spear-form element adapted to pierce tissue and has a retaining barb

10 on its distal end. The device includes a cutting guide on the outer surface of the body of the device proximal of the tissue-receiving opening. The guide is formed by a slot including a cutting edge with a portion communicating with the periphery of the opening such that

15 tissue prolapses into the slot when the periphery of the device is placed against the tissue surface. The device is rotatable about its axis so that tissue in the slot is cut by the cutting edge and tissue passes through the tissue-receiving opening. The depth of the cut and the

20 width of tissue passing through the opening is determined by the degree of rotation of the body and the width of the guide. The depth of the cut is about 1-2 mm for each rotation of the device. The severing element is a cutting edge positioned to extend radially across the

25 opening. The element is actuatable to sever tissue by rotation of the wire across the opening of the device body. The cutting edge is a cutting wire extending across the diameter of the opening. The wire is attached under tension at its opposite ends to the body of the

30 device. The wire is actuatable to sever tissue by rotation of the device about its axis. The storage portion includes apertures through the wall of the device. The storage portion includes a low friction coating to improve axial sliding of tissue samples.

- 4 -

In another aspect, the invention features a method for collecting from a sample surface, a sample of tissue, including specimens, polyps, or the like. The method includes providing a sampling device that has a device  
5 body defining a forward-facing tissue receiving opening of substantially predetermined width through which tissue may pass when the opening is near the tissue surface, and a severing element actuatable across the width of the tissue receiving opening when tissue from the surface  
10 extends through the opening for severing the tissue from the surface. The method includes positioning the device near the tissue surface, receiving tissue through the tissue-receiving opening, and actuating the severing element to sever a tissue sample from the surface.

15       Embodiments may include one or more of the following. The method includes providing the sampling device at the end of an elongate flexible member, and delivering the device by threading the device through the body to a desired tissue surface deep within the body.  
20 The method includes providing a sampling device that further includes a storage space proximal of and adjacent the opening for storage of multiple successively taken samples by repeatedly passing tissue through the opening and actuating the severing element, and taking multiple  
25 samples by repeating the steps of positioning and actuating to take multiple samples without removing the device from the body. The method includes rotating the device as it is urged forward into tissue.

The invention has many advantages. For example,  
30 sampling into tissue to a desired depth can be achieved by controlling the amount of sample that enters the forward-facing coring opening of the device, by, for example, controlling how deeply the device is advanced into a tissue wall or how much tissue is drawn through  
35 the opening using a retractor. Thick samples can be

- 5 -

taken in a single sampling action; for example, samples beyond the mucosal layer (submucosal sampling) can be taken from a site in a single sampling action. Careful control of sampling depth also permits samples to be taken from very thin tissue walls without puncturing the walls. Multiple samples can be taken, stored in the device, and maintained in a hydrated state without removing the device from the body.

Further advantages follow.

10                   Brief Description of the Drawing

We first briefly describe the drawings.

Fig. 1 is a perspective view of an embodiment of the invention being delivered into the body through an endoscope;

                  Fig. 3 illustrates the structure and use of another embodiment of the invention;

                  Figs. 4-4e illustrate the structure and use of another embodiment of the invention;

                  Figs. 5-5e illustrate the structure and use of yet another embodiment of the invention;

                  Fig. 6 illustrates the structure and use of another embodiment of the invention;

25                   Figs. 7-7c illustrate the structure and use of another embodiment of the invention.

Description of the Preferred Embodiments

Referring to Fig. 1, the device 10 for multiple biopsy sampling may be delivered into the body through the channel of an endoscope device 11 (e.g., gastroscope, sigmoidoscope, or colonoscope). The endoscope device typically has a length of about 100-250 cm and a channel diameter of 2.0 - 3.8 mm, typically about 2.8 mm. A distal sampling portion 16 is extended from the endoscope for cutting and storing a sample of tissue from a body

- 6 -

surface 18 of a patient (e.g. from a surface in the gastrointestinal tract or bronchial tract). The device has a diameter of preferably around 1.8 - 2.4 mm, typically about 2.3 mm or less and is of sufficient flexibility so it passes easily through the channel when the endoscope follows a tortuous body passageway. The endoscope includes other lumens for water, air, suction, and viewing. Devices according to the invention can be adapted to be introduced to sites (e.g., urinary tract, reproductive organs, cardiac tissue, or the like) deep within the body by other means. For example, a device can be configured with a lumen so that it can be advanced over a guidewire, e.g., in vascular applications. The device may be passed through an introducer or guiding catheter in, e.g., cardiac applications. The sampling and storage arrangements may be useful in open surgery applications, in breast biopsy in which the device is pressed directly into tissue, laproscopic biopsy in which the cutting element is positioned through a tubular instrument extending through the skin, and percutaneous needle biopsy in which the device is directed through a hole in the skin to sample an internal organ, e.g., the liver.

Referring to Figs. 2-2e, in an embodiment, sampling portion 16 includes an inner tubular sample holding and coring member 20 and an outer cutting member 22. The inner tubular member 20 defines in its proximal portions an inner space 25 for storage of multiple, successively taken biopsy samples. As shown particularly in Figs. 2a et seq., the samples are stored adjacent one another in the order in which they are taken. A sample stop 23 defines the most proximal end of the space 25. The stop 23 can be moved axially distally to retrieve the multiple samples after the device is removed from the body, as will be discussed in more detail below. The

- 7 -

distal end of the inner tubular member defines a forward-facing, tissue-receiving opening 19 and is sharpened to a cutting edge 24.

The outer cutting member 22 includes near its distal end a pair of moveable jaw-like cutting elements 26, 26a. The cutting elements are formed of a material having substantial elasticity, for example, a shape memory alloy or stainless steel, and worked such that the cutting elements are biased toward the closed position. The cutting member 22 and the inner tubular member 20 are axially movable with respect to one another (arrows 21, 21'). In the configuration shown in Fig. 2, with the inner tubular member extended distally somewhat with respect to the cutting member 22, the distal end of the cutting member bears on the inner surfaces 27, 27a of the elements 26, 26a, moving them radially into an open position (arrow 29). The outer edges 28, 28a of the cutting elements are sharpened for cutting tissue, as will be further described below.

In embodiments, other cutting element arrangements are possible; for example, elements that rotate about a pivot point and are biased by a spring could be provided. Arrangements with more than two cutting elements may also be used. One of either the cutting member or tubular member may be moveable and the other stationary. The components that experience sliding motion may include a lubricant. For example, the interior wall of the inner tubular member may include a low friction coating 17, e.g., of teflon, silicone, or a hydrogel, so that samples within the tube and storage space slide easily. The outer surface of the inner tubular member and/or the inner surface of the outer tubular member may also include a lubricant to ease sliding motion. (Other sliding components in other embodiments, shown below,

- 8 -

e.g., control wires and cutting loops may also include a lubricant.)

Referring particularly to Fig. 2a, (cross-sectional view), in use, the inner tubular member is  
5 extended distally to open the cutting elements and extend beyond them so the edge 24 cuts into a surface 18 of tissue to a depth that approximates the desired depth to which a sample is to be taken. The tubular member is rotated slightly about its axis as it is urged forward to  
10 create a shearing action that aids cutting.

Referring particularly to Fig. 2b, the sample is severed from the tissue surface 18 by extending the outer cutting member 22 distally (arrow 32). When the cutting member 22 has extended sufficiently beyond the distal  
15 edge of the inner tubular member 20, the cutting elements 26, 26a begin to close (arrows 27) and the cutting edges 28, 28a sever the tissue sample from the body surface 18. The cutting member may be rotated slightly about its axis as it is extended forward to create a shearing action to  
20 facilitate cutting. As tissue enters the inner tubular member it pushes the previously-taken samples, samples 1-4, proximally in the space 25.

Referring particularly to Fig. 2c, after the cutting member 22 has been extended distally such that  
25 the cutting elements 26, 26a are completely closed, the new sample, sample 5, is cut completely free of the tissue surface 18.

Referring particularly to Fig. 2d, the device 16 can be moved to a new location for taking an additional  
30 sample by repeating the steps above. Thus, multiple samples can be taken without removing the device from the body.

Referring to Fig. 2e, after a sufficient number of samples have been taken, and the device has been removed  
35 from the body, samples 1-5, stored in the space 25 in the

- 9 -

order in which they were taken, can be recovered by again extending the inner tubular member 20 in the distal direction to force open the cutting elements 26, 26a. The stop member 23 is then extended distally (arrow 38) to push the samples sequentially from the end of the tubular member.

Referring to Fig. 3, another embodiment is shown. In this case, a retractor 40 is provided. The retractor member is axially movable (arrow 41), is formed of an extended length, and has a barbed tip 42 for piercing and retaining samples during axial travel. In use, the inner tubular member 20 is extended to open cutting elements 26, 26a and to rest against the tissue surface 18. The distal end of the tubular member may include, but does not require, a sharp cutting edge. The retractor 40 is then extended distally into the surface 18, thus displacing previous samples 1-4 proximally along its body. The retractor 40 is then withdrawn proximally drawing a piece of tissue into the distal end of the tubular member 20, as shown in Fig. 3. The cutting member 22 can then be moved distally to close the cutting elements 26, 26a and sever the sample from the surface 18. Other retractors can be used, such as hooks, tongues, and helical screw elements as described, for example, in "Multiple Biopsy Sampling Device", by Bruce H. Diamond, Donald E. Robinson, Alyssa J. Dassa, and Charles Warich, U.S. Serial No. 08/124,272, filed September 20, 1993, the entire contents of which is hereby incorporated by reference. Also incorporated by reference is "Multiple Biopsy Sampling Forceps" by Alyssa J. Dassa and Bruce H. Diamond, U.S. Serial No. 08/128,653, filed September 30, 1993.

The embodiment of Fig. 3 can also be used by providing the tubular member with a sharpened distal end and extending the tubular member 20 into the tissue, as

- 10 -

described above with respect to Figs. 2 et seq. The retractor is positioned so it pierces the tissue that passes through the distal opening. However, rather than pushing the cutting member 22 in the distal direction to close the jaws, the tubular member 20 and retractor 40 are withdrawn proximally together relative to the moveable cutting elements, which close to sever the sample. The cutting member may be rotated as the inner tubular member is drawn proximally, to cause a shearing action that enhances cutting.

Referring to Figs. 4-4e, another embodiment is shown. In this embodiment, a tubular member 50 defines at its distal end, a forward-facing distal opening 52 and includes within a retractor 54, preferably a spear-form element with a barb as shown, or another retractor type as discussed above. The retractor 54 is axially movable (arrow 56) and extends through a storage space 58 bounded on the proximal end by a sample stop 60. The axial motion of the retractor 54 and stop 60 are controlled separately; the retractor passes through an aperture in the stop and the stop is controlled by a separate member 61. (Alternatively, in other embodiments, the retractor may be attached to the stop so they move axially together.)

The embodiment also includes a wire-form cutting loop 64. The loop, shown extended in Fig. 4, is oriented with its center roughly along the axis of the device and sized to approximate or be larger than the outer diameter of the distal portion of tubular member 50. The loop 64 may be formed of a shape memory metal, e.g., nitinol or other elastic materials, such as cold-worked stainless steel, or a plastic, that can be preformed and trained so it is capable of being repeatedly withdrawn into a lumen 62, where the loop is in a compacted state, and then extended therefrom to open and orient the loop as shown.

- 11 -

A control wire 65, for retracting and extending the loop, may be made integrally or attached to the loop. The lumen 62 may be constructed integrally with the tubular member 50.

5 Referring particularly to Fig. 4a (cross-sectional view), in use, the control wire 65 is extended distally so the cutting loop 64 is formed and positioned just distal of the open end 52 of the device 50, which is brought in proximity of the surface 18 where a sample is  
10 be taken. The retractor 54 is extended distally (arrow 66) so it pierces the tissue surface 18. As the retractor 54 is extended distally, previously taken samples, samples 1-4, are displaced proximally.

Referring particularly to Fig. 4b, the retractor  
15 54 is then withdrawn proximally (arrow 68), bringing tissue into the distal end opening of the member 50 and through the cutting loop 64.

Referring particularly to Figs. 4c, 4d (end on view, tissue not shown) and 4e, the tissue sample is  
20 severed from the surface 18 by withdrawing the control wire 65 proximally, which draws the loop 64 through tissue across the end opening 52 of the member 50. With the loop 64 substantially withdrawn in the lumen 62, the new sample, sample 5, is completely severed from the  
25 surface 18 (Fig. 4e). The process can be repeated by extending control wire 65, distally and hence forming the cutting loop 64, to cut the next sample, as shown in Fig. 4a.

Referring to Figs. 5-5e, another embodiment is  
30 shown. In this case, the device includes near the end opening 54, a cutting guide 70, formed in the wall of the tubular body adjacent the distal end. (The guide does not extend across the diameter of the end opening; rather, it is formed by cutting out a portion of the side  
35 wall of a tube.) The device further includes a cutting

- 12 -

loop 72, having an open diameter larger than the diameter of the end 54 of the device.

In this embodiment, the depth of the sample cut can be carefully and conveniently controlled. The end 54 of the device is pressed against the tissue wall. (The end need not be sharpened to a tissue-cutting edge.) Tissue prolapses into the gap 76 proximal of the cutting guide 70. The gap is bordered by sharpened cutting edges 78, 78'. Thus, tissue cutting occurs only during rotation of the device. The depth of tissue cut during rotation is controlled by the width of the cutting guide W from the end 54 of the device to the lower-most proximal portion of the cutting edge 78. Thus, for a single rotation, a helical, circumferential cut through tissue is made to a depth no greater than the width W.

The cutting loop 72, of an enlarged diameter, slides distally over the body of the device as the distal end enters the tissue. The loop 72 can be retracted to sever the sample of controlled depth from the body surface. An axially movable retracting arm 74, passing through a slotted lumen 76, may also be provided to pull samples into the body of the device for storage. The lumen slot 77 allows the radially extending arm to be withdrawn proximally. An optional stop member 80, in this case a conical member that widens to greater diameter in the distal direction, can be positioned on the device to assure that coring beyond a predetermined depth does not occur. The stop member can be an umbrella-type assembly that changes the axial location of the end of the stop by opening and closing radially, as shown. Other stop mechanisms, such as an inflatable balloon or a spring-form wire may also be used. Apertures 82 are placed in the body of the device so that fluids (e.g. ambient body fluids) can easily pass to contact previously taken samples while they are being

- 13 -

stored to keep them from drying out, which can damage cell structure and make pathological examination more difficult. Saline solution or the like may also be passed from proximal portions e.g. through the main  
5 lumen, into contact with samples. The saline may flow out of the apertures 82.

The body of the device is preferably formed of a highly torqueable plastic tube, but for the distal end including the cutting tang 70, which is preferably formed  
10 of metal. The proximal portions of the device include a wire coil body 83 that can be passed through torturous passageways, e.g., an endoscope channel. The shape of the guide can be varied to affect various depths and cutting profile. Typically, the most distal end of the  
15 guide terminates in a sharp point, as shown, to help start the cutting when rotation begins. The control wire and/or the cutting loop may be made of braided wires. The cutting loop may be shaped along its inner edge to form a sharp cutting surface. The cutting loop may also  
20 be heated e.g., by electric current. The end of the tubular member may flare outward, distally to facilitate drawing tissue into the end.

Referring particularly to Fig. 5a, in use, the enlarged cutting loop 72 is extended and the distal end  
25 of the device, including front-facing surface of the cutting guide 70, is pressed against the surface 18 of tissue from which a sample is to be taken. Tissue prolapses into the gap 76 of the cutting guide. (This embodiment does not include retractor 74 or stop 80. The mechanical  
30 simplicity of this embodiment is an advantage, since, it can be delivered through tighter lumen tracts to hard-to-reach sampling sites.)

Referring particularly to Fig. 5b, the body of the device is pressed against the tissue and rotated about

- 14 -

its axis (arrow 88), causing tissue in the gap 76 to be cut by the sharpened edges 78, 78'.

Referring particularly to Fig. 5c, as the distal end of the device enters the tissue due to the rotating cutting motion, the cutting loop 72 is pushed proximally, over the outside of the body.

Referring particularly to Fig. 5d, when the device has entered the tissue to a desired depth, for example, a single rotation of the device cutting to a depth equal to the width of the guide, a sample can be severed from the tissue surface 18 by withdrawing the cutting loop 72 into the lumen 52. The cutting loop, drawn back into the lumen 62 over the body, cuts the tissue across the opening of the distal end of the device.

Referring particularly to Fig. 5e, with the cutting loop 72 drawn substantially completely into the lumen 52, a thickness-controlled sample is severed from the tissue surface 18. The procedure above can be repeated to take an additional sample if desired.

Referring to Fig. 6, another embodiment is shown. In this case, the device includes a tubular member 100, having an open tubular distal end 102. The distal end 102 is sharpened so the device may be urged into tissue to a desired depth, by extending the device distally axially. A cutting wire 104 is provided across the circumference of the device. To sever a tissue sample, the body of the device is rotated about its axis (arrow 106). For each sample taken, the device produces two sample halves. For example, sample halves 110, 112 of sample 108, since the tissue has been bisected by the cutting wire 104 when the device was urged distally into the tissue surface. The device may further be provided with retractor members 114, 116, which may be in the form of a spear-form element or other retractors as described above.

- 15 -

Referring to Figs. 7-7c, another embodiment for severing tissue is shown. In this case, an arrangement for severing tissue across the distal end 130 of a tube 132 includes a pair of wire cutting elements 134, 136, 5 that join at respective ends to control wires 138, 139, that are axially moveable in lumens 140, 141. In the configuration shown in Figs. 7 and 7a (end-on view), the control wires are extended, which bows the wire cutting elements 134, 136 outward, causing them to conform to the 10 outer end of the tubular member so that tissue can extend beyond the wires and enter the distal end of the tube. In the configuration of Figs. 7b and 7c, the control wires are drawn proximally, causing the cutting elements 134, 136 to close across the end opening of the tube, 15 cutting tissue so that a sample can be severed from a tissue surface. In other embodiments, a single control wire is used; the other ends of the cutting elements are attached to the end of the tube.

The features discussed above with respect to the 20 various embodiments, e.g. arrangements for receiving tissue through the opening of the devices and arrangements for severing tissue from a surface, can be combined in further embodiments.

Still further embodiments are within the following 25 claims.

- 16 -

1. A device for collecting from a tissue surface, a sample of tissue, including tissue specimens, polyps, or the like, comprising:

a device body defining a forward-facing tissue  
5 receiving opening of substantially predetermined width  
through which tissue may pass when said opening is near  
said tissue surface,

a severing element actuatable across the width of  
said tissue receiving opening when tissue from said  
10 surface extends through said opening for severing said  
tissue from said surface, and

a storage space proximal of and adjacent said  
opening for storage of multiple successively taken  
samples by repeatedly passing tissue through said opening  
15 and actuating said severing element.

2. The device of claim 1 wherein said severing  
element comprises a set of moveable, jaw-like cutting  
members actuatable to be opened and closed for severing  
tissue from said surface to take said sample,

20 said cutting members being coaxially disposed and  
axially positionable with respect to said tissue  
receiving opening such that said device is positionable  
between a first configuration in which the cutting  
members are proximal of said opening for receiving tissue  
25 through said opening and a second configuration in which  
the cutting members are near said opening where said  
cutting members can be closed to sever tissue and take  
said sample.

3. The device of claim 2 wherein said cutting  
30 members are disposed over the device body.

4. The device of claim 3 wherein said cutting  
members are biased closed,

- 17 -

said cutting members are opened by disposing said device in the first configuration, where said cutting members bear on outer surfaces of the body which oppose the force of said bias, and

5        said cutting members are closed by disposing said device in the second configuration where said jaws are free from said body and close in response to said bias force.

5.        The device of claim 3 or 4 wherein said  
10 forward-facing tissue receiving opening is defined about its periphery by a tissue-cutting edge, said tissue passing through said opening by urging said edge distally into said tissue surface.

6.        The device of claim 1 or 4 wherein said  
15 device further comprises an axially movable retractor for engaging a tissue and drawing it proximally.

7.        The device of claim 6 wherein said retractor is extendable distally beyond said opening for engaging said tissue surface and retractable proximally to draw  
20 tissue through said tissue-receiving opening.

8.        The device of claim 7 wherein said retractor is a spear-form element adapted to pierce tissue and has a retaining barb on its distal end.

9.        The device of claim 1 wherein said severing  
25 element comprises a cutting loop, said cutting loop being actuatable between an open configuration that is oriented generally coaxially with said tissue-receiving opening and a closed configuration in which the loop passes across said opening to sever said tissue.

- 18 -

10. The device of claim 9 wherein said cutting loop is actuated by a control wire extending parallel with the axis of said body.

11. The device of claim 10 wherein said control  
5 wire passes through a lumen extending to an opening adjacent said tissue-receiving opening.

12. The device of claim 11 wherein said cutting loop is actuated by withdrawing it into said lumen.

13. The device of claim 9 including a retractor  
10 extendable distally beyond said opening and said cutting loop for engaging said tissue surface and retractable proximally to draw tissue through said tissue-receiving opening and cutting loop.

14. The device of claim 13 wherein said retractor  
15 is a spear-form element adapted to pierce tissue and having a retaining barb on its distal end.

15. The device of claim 1 or 9 further including a cutting guide on the outer surface of the body of the device proximal of said tissue-receiving opening, said  
20 guide formed by a slot including a cutting edge with a portion communicating with the periphery of said opening such that tissue prolapses into said slot when the periphery of said device is placed against said tissue surface,

25 said device being rotatable about its axis so that tissue in said slot is cut by said cutting edge and tissue passes through said tissue-receiving opening, the depth of said cut and the width of tissue passing through said opening being determined by the degree of rotation  
30 of said body and the width of said guide.

- 19 -

16. The device of claim 15 wherein the depth of said cut is 1-2 mm for each rotation of said device.

17. The device of claim 1 wherein said severing element is a cutting edge positioned to extend radially  
5 across said opening, said element being actuatable to sever tissue by rotation of said wire across the opening of said device.

18. The device of claim 17 wherein said cutting edge is a cutting wire extending across the diameter of  
10 said opening, said wire attached under tension at its ends to the body of said device, the wire actuatable to sever tissue by rotation of the device about its axis.

19. The device of claim 1 wherein said storage space includes apertures communicating with hydrating  
15 fluids.

20. A method for collecting from a sample surface, a sample of tissue, including specimens, polyps, or the like, comprising:

providing a sampling device including:

20 a device body defining a forward-facing tissue receiving opening of substantially predetermined width through which tissue may pass when said opening is near said tissue surface,  
a severing element actuatable across the  
25 width of said tissue receiving opening when tissue from said surface extends through said opening for severing said tissue from said surface, and  
positioning said device near said tissue surface, receiving tissue through said tissue-receiving  
30 opening, and

- 20 -

actuating said severing element to sever a tissue sample from said surface.

21. The method of claim 20, comprising:  
providing said sampling device at the end of an  
5 elongate flexible member, and  
delivering said device by threading said device through the body to a desired tissue surface deep within the body.

22. The method of claim 20, comprising:  
10 providing a sampling device that further includes a storage space proximal of and adjacent said opening for storage of multiple successively taken samples by repeatedly passing tissue through said opening and actuating said severing element, and  
15 taking samples by repeating said steps of positioning and actuating to take multiple samples without removing said device from the body.

## INTERNATIONAL SEARCH REPORT

International application No.  
PCT/US94/10565

## A. CLASSIFICATION OF SUBJECT MATTER

IPC(6) :A61B 5/00

US CL :128/754

According to International Patent Classification (IPC) or to both national classification and IPC

## B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

U.S. : 128/751-754; 606/167, 170

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched  
NONEElectronic data-base consulted during the international search (name of data base and, where practicable, search terms used)  
NONE

## C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.

* Special categories of cited documents:	* T later document published after the international filing date or priority date and not in conflict with the application cited to understand the principle or theory underlying the invention
* A* document defining the general state of the art which is not considered to be part of particular relevance	* X* document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
* E* earlier document published on or after the international filing date	* Y* document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art
* L* document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)	* &* document member of the same patent family
* O* document referring to an oral disclosure, use, exhibition or other means	
* P* document published prior to the international filing date but later than the priority date claimed
